	<b>Python Module Index</b>	<b>17</b>

Welcome to Deeptracy's documentation. This documentation is divided into two different parts. One is the userdocs-ref which include installation and usage, and the other is the *Developer's Documentation* which include sourcecode-ref documentation, local environment, testing and so on.

# CHAPTER 1

---

## Quick start

---

This document is a quick introduction for use Deeptracy Service

### 1.1 First of run Patton Server

#### 1.1.1 1 - Install Docker Compose

Install Docker Compose from this link

#### 1.1.2 2 - Create a docker-compose.yml file

Download Docker Compose file from [this link](#) or copy this code

```
version: '3'

services:

  postgres:
    image: postgres:9.6-alpine
    environment:
      - POSTGRES_PASSWORD=postgres
    ports:
      - 5433:5433
    command: -p 5433

  redis:
    image: redis:3-alpine
    ports:
      - 6379:6379

  deeptracy:
    image: bbvalabs/deeptracy
```

```
depends_on:
  - redis
  - postgres
environment:
  - BROKER_URI=redis://redis:6379
  - DATABASE_URI=postgresql://postgres:postgres@postgres:5433/deeptracy
  - POSTGRES_URI=postgresql://postgres:postgres@postgres:5433
  - SHARED_VOLUME_PATH=/tmp/deeptracy
  - LOCAL_PRIVATE_KEY_FILE=/root/.ssh/id_rsa
  - PATTON_URI=http://0.0.0.0:8000
  # - EMAIL_SMTP_SERVER=xxx.xxx.xxx
  # - EMAIL_SMTP_PORT=xxx
  # - EMAIL_SMTP_USER=xxx@xxx.xxx
  # - EMAIL_SMTP_PASSWORD=xxxxxx
  # - EMAIL_FROM=xxx@xxx.xxx
ports:
  - 8000:8000
volumes:
  - /var/run/docker.sock:/var/run/docker.sock
  - /tmp:/tmp
  - ./private_key:/root/.ssh/
privileged: true
command: ["./init_patton_db.sh"]

deeptracy-api:
  image: bbvalabs/deeptracy-api
  depends_on:
    - redis
    - postgres
  ports:
    - 8080:8080
  environment:
    - BROKER_URI=redis://redis:6379
    - DATABASE_URI=postgresql://postgres:postgres@postgres:5433/deeptracy
    - SERVER_ADDRESS=0.0.0.0:8080
    - GUNICORN_WORKERS=1
    - LOG_LEVEL=INFO
  command: ["./wait-for-it.sh", "postgres:5433", "--", "/opt/deeptracy/run.sh"]
```

### 1.1.3 3 - Execute the docker-compose file

```
> docker-compose up
```

### 1.1.4 4 - ENJOY DEEptracy WITH PATTON

# CHAPTER 2

---

## User's Documentation

---

This documentation is for users who want to use Deeptracy. It covers two parts, *Installation* and *Usage*

### 2.1 Installation

#### 2.1.1 Components

Deeptracy has four main components:

- *Deeptracy Workers* these are celery workers that process tasks
- *Deeptracy API* this is the main entrance for actions
- *Deeptracy Dashboard* this is the dashboard for visual information on the system
- plugin-ref there is a plugin for each scan tool

Each of this components is shipped as a docker image. You can find them in the public deeptracy dockerhub <https://hub.docker.com/search/?isAutomated=0&isOfficial=0&page=1&pullCount=0&q=deeptracy&starCount=0>.

Beside the components of Deeptracy, the system needs two more things to work:

- *Postgres* database to store projects, scans and so on
- *Redis* in-memory data structure store used as message broker

This two components can be launched as a docker containers, but you can also install them without docker.

#### 2.1.2 Deeptracy Workers

Workers are celery processes. You can launch any number of workers **on the same hosts**. As they are celery workers connected to a broker (redis), they will take tasks to even the workload.

One of the tasks performed by the workers is cloning repositories. For this, you need to **mount a the same volume in each worker from the host**, where the repositories will be cloned. This volume (*SHARED\_VOLUME\_PATH*) will be mounted in various containers that the worker uses to perform distinct tasks.

**Warning:** Because the repository to scan is only downloaded once, you can't have workers on different hosts, as the source code for the project is only present in the hosts that perform the task to download it.

The workers performs almost all the task inside docker containers. The worker image has docker installed, but you can mount the docker socket from the host in to the worker containers, so the docker in the host would be used.

### Environment Variables

This are the environment variables needed by the workers

- **BROKER\_URI** Url to the redis broker (Ex. redis://127.0.0.1:6379)
- **DATABASE\_URI** Url to the postgres database (Ex. postgresql://postgres:postgres@127.0.0.1:5433/deeptracy)
- **PATTON\_URI** Url to the patton server(Ex. <http://localhost:8000>)
- **SHARED\_VOLUME\_PATH** Path in the host to mount as a volume in Docker images. this folder is going to be used to clone projects to be scanned. (Ex. /tmp/deeptracy)
- **LOCAL\_PRIVATE\_KEY\_FILE** If you wanna clone private repositories, you can specify a private key file to be used when cloning such repos.
- **LOG\_LEVEL** The log level for the application (Ex. INFO)

### Docker Compose Example

```
deeptracy:  
    image: bbvalabs/deeptracy  
    depends_on:  
        - redis  
        - postgres  
    environment:  
        - BROKER_URI=redis://redis:6379  
        - DATABASE_URI=postgresql://postgres:postgres@postgres:5433/deeptracy  
        - SHARED_VOLUME_PATH=/tmp/deeptracy  
        - LOCAL_PRIVATE_KEY_FILE=/tmp/id_rsa  
        - PLUGINS_LOCATION=/opt/deeptracy/plugins  
    volumes:  
        - /var/run/docker.sock:/var/run/docker.sock  
        - /tmp:/tmp  
    privileged: true  
    command: ["./wait-for-it.sh", "postgres:5433", "--", "/opt/deeptracy/run.sh"]
```

## 2.1.3 Deeptracy API

## 2.1.4 Deeptracy Dashboard

## 2.1.5 Bringing up the environment

As all the pieces are shipped as Docker containers, is easy to bring up an environment. You can find an example with code to launch Deeptracy in a single AWS instance in the [deploy](#) folder.

This is an example of a complete Docker Compose file that launch a complete working environment.

```
version: '3'

services:
  deeptracy:
    image: bbvalabs/deeptracy
    depends_on:
      - redis
      - postgres
    environment:
      - BROKER_URI=redis://redis:6379
      - DATABASE_URI=postgresql://postgres:postgres@postgres:5433/deeptracy
      - SHARED_VOLUME_PATH=/tmp/deeptracy
      - LOCAL_PRIVATE_KEY_FILE=/tmp/id_rsa
      - PLUGINS_LOCATION=/opt/deeptracy/plugins
    volumes:
      - /var/run/docker.sock:/var/run/docker.sock
      - /tmp:/tmp
    privileged: true
    command: ["./wait-for-it.sh", "postgres:5433", "--", "/opt/deeptracy/run.sh"]

  deeptracy-api:
    image: bbvalabs/deeptracy-api
    depends_on:
      - redis
      - postgres
    ports:
      - 80:8080
    environment:
      - BROKER_URI=redis://redis:6379
      - DATABASE_URI=postgresql://postgres:postgres@postgres:5433/deeptracy
      - SERVER_ADDRESS=0.0.0.0:8080
      - GUNICORN_WORKERS=1
    command: ["./wait-for-it.sh", "postgres:5433", "--", "/opt/deeptracy/run.sh"]

  postgres:
    image: postgres:9.6-alpine
    ports:
      - 5433:5433
    environment:
      - POSTGRES_PASSWORD=postgres
    command: -p 5433

  redis:
    image: redis:3-alpine
    ports:
      - 6379:6379
```

This docker compose will bring up an environment with a single worker and the API listening in the port 80 of the host.

## 2.2 Usage

This section explain how to use Deeptracy. Once installed Deeptracy can be used as a service. This means that a public API is exposed and all functionalities can be used through it.

### 2.2.1 Create Projects

Projects are the main object in the API. A project represents a single repository that you want to scan and monitorice for vulnerabilities. You can't have more than one project with the same repository in the database.

To create projects you need to invoke the [\*Create Projects\*](#) endpoint after any scan.

### 2.2.2 Launch Scans

Every time a scan is launched, Deeptracy will check for the project dependencies. **If the dependencies have changed from the last scan performed, the scan will begin.**

A scan is performed by cloning the project repository and running different plugins against the source code. You can launch scans manually by calling the [\*Create Scan\*](#) endpoint or by [\*Configuring a hook for your project\*](#).

### 2.2.3 Spot Vulnerabilities

Evey scan will run N analyzers (one for each plugin available in the system) and save the vulnerabilities found on the database. Once all analyzers are done, all vulnerabilities are merged together and saved as a final vulnerability list.

You can access individual analyzer results with [\*Get Analyzer Vulnerabilities\*](#) endpoint or the final scan list with the [\*Get Scan Vulnerabilities\*](#) endpoint.

### 2.2.4 Get Notified

Every time a scan finishes, if your project have the information to receive notifications you will receive one with the spotted vulnerabilities.

### 2.2.5 Configuring a hook for your project

You can configure a hook in your repository, so every time a push is detected a scan will automatically launched for your project. The url for the hook is {host}/api/1/webhook/

- [Github](#) Create a webhook for *PUSH* actions only
- [Bitbucket](#) Create a webhook for *PUSH* actions only

## 2.3 API Reference

This section of the documentation exposes the API methods availables to interact with.

**2.3.1 Create Projects**

**2.3.2 Create Scan**

**2.3.3 Get Analyzer Vulnerabilities**

**2.3.4 Get Scan Vulnerabilities**

# CHAPTER 3

---

## Developer's Documentation

---

This documentation is for developers who want to contribute to Deeptracy.

### 3.1 Installation

#### 3.1.1 Python Version

We recommend using the latest version of Python 3. Deeptracy supports Python 3.6 and newer.

#### 3.1.2 Deeptracy Projects

Deeptracy has four repositories with each of its components:

- `Workers` main repository with celery tasks and plugins
- `Api` holds the Flask API
- `Dashboard` has the front web
- `Core` shared library between workers and api projects. Data access components and plugins perks.

For develop, is recommended that you clone each repository under the same work dir:

```
- deeptracy-project
| - deeptracy
| - deeptracy-api
| - deeptracy-core
| - deeptracy-dashboard
```

### 3.1.3 Virtual environments

Is highly recommended to work with a single virtual environment for all the projects by creating a single environment at the same level that the rest of the projects

```
- deeptracy-project
| - deeptracy
| - deeptracy-api
| - deeptracy-core
| - deeptracy-dashboard
| - .venv
```

### 3.1.4 Deeptracy Core

Deeptracy core is a shared library that has common functionalities used in the rest of the projects. When developing is recommended to install it in your virtualenv in [editable mode](#):

```
$ cd deeptracy-core
$ pip install -e .
```

This will instruct distutils to setup the core project in to development mode

### 3.1.5 Deeptracy Workers

This project is a [Celery](#) project. You can install it with:

```
$ cd deeptracy
$ make install-requirements_dev
```

### 3.1.6 Deeptracy API

This project is a [‘Flask’](#) project. You can install it with:

```
$ cd deeptracy-api
$ make install-requirements_dev
```

### 3.1.7 Dependencies

These distributions will be installed automatically when installing Deeptracy.

- [Celery](#) is an asynchronous task queue/job queue based on distributed message passing
- [Redis](#) in-memory data structure store used as message broker in celery
- [Psycopg](#) PostgreSQL database adapter for Python
- [Pluginbase](#) for plugin management
- [Docker](#) most tasks are executed inside docker containers
- [PyYAML](#) parse yml files

### 3.1.8 Development dependencies

These distributions will be installed for development and local testing

- [Bumpversion](#) control the version numbers in releases.
- [Sphinx](#) documentation generation
- [Flake8](#) for linting and code style
- [Coverage](#) checks code coverage
- [Behave](#) acceptance tests

## 3.2 Usage

### 3.2.1 Makefiles & Dotenv

To standardize tasks among repositories, each repository have a `Makefile` that can be used to perform common tasks. By executing `make` in the root of each project you can get a detailed list of tasks that can be performed.

When executing tasks with `make`, we also provide a `.dot-env` mechanism to have local environment variables for each project. So, the first time you perform any `make` task, you will be prompted for the required environment variables for that project.

Keep in mind that you can always change the local environment for a project by editing the `.env` file generated in the project root folder.

This is a sample of common tasks that can be performed with `make`:

```
$ make
clean           remove all build, test, coverage and Python artifacts
test            run tests quickly with py.test
test-all        run tests on every python version with tox
lint            check style with flake8
coverage        check code coverage
docs            generate and shows documentation
run             launch the application
at_local        run acceptance tests without environemnt. You need to start your_
                ↵own environment (for dev)
at_only         run acceptance tests without environemnt, and just features_
                ↵marked as @only (for dev)
at              run acceptance tests in complete docker environment
```

### 3.2.2 Local environment

You can have a full functional working local environment to do integration or acceptance tests. En the workers and API projects you can find a `docker-compose-yml` file that will launch a postgres and a redis container:

```
$ cd deeptracy
$ docker-compose up
```

Once the database and the broker are in place, now you can launch each project issuing a `make run` on each of them.

### 3.2.3 Development flow

You should be doing unit test to test the new features. When you are working in **deeptracy** or in **deeptracy-api** is likely you will also need to work in **deeptracy-core**. If you installed the core in *Deeptracy Core* you will see the changes in the core from the other projects as soon as they are made.

Once the new feature is covered and tested with unit tests, you can launch a *Local environment* and run the acceptance tests in the local environment with `make at_local`

## 3.3 Testing

### 3.3.1 Unit Tests

For development is recommended to do unit tests to speedup the process (you don't need a full environment), and only do acceptance and integration tests when the feature is ready and tested with unit tests.

**Warning:** Pipelines has a check on whether the test coverage has a minimum of code covered, so lowering the percentage of lines of code covered by unit tests is not an option. You can check your code coverage with `make coverage`

### 3.3.2 Acceptance Tests

### 3.3.3 Code Coverage

# CHAPTER 4

---

Source Code Docs

---

## 4.1 deeptracy package

### 4.1.1 Subpackages

`deeptracy.notifications` package

Submodules

`deeptracy.notifications.slack_webhook_post` module

Detailed documentation of Slack Incoming Webhooks: <https://api.slack.com/incoming-webhooks>

`deeptracy.notifications.slack_webhook_post.notify(webhook_url: str, text)`

Module contents

`deeptracy.tasks` package

Submodules

`deeptracy.tasks.base_task` module

This module contains base class for all celery task in deeptracy and other common classes used in all tasks

`class deeptracy.tasks.base_task.DeeptracyTask`  
Bases: `celery.app.task.Task`

Default class for all task in deeptracy. It has error handling for logging all celery failures in tasks

`on_failure(exc, task_id, args, kwargs, einfo)`

```
exception deeptracy.tasks.base_task.TaskException
Bases: BaseException
Exception for use in controlled errors inside tasks
```

[deeptracy.tasks.notify\\_results module](#)

[deeptracy.tasks.prepare\\_scan module](#)

[deeptracy.tasks.scan\\_deps module](#)

[deeptracy.tasks.notify\\_patton\\_deltas module](#)

## Module contents

### 4.1.2 Submodules

[4.1.3 deeptracy.celery module](#)

[4.1.4 deeptracy.config module](#)

### 4.1.5 Module contents

Deeptracy Workers Project.

This package contains celery workers and tasks to process the deeptracy flow for scanning projects.
